27 Abstract

The ability to rapidly recognize words and link them to referents in context is central to

²⁹ children's early language development. This ability, often called word recognition in the

developmental literature, is typically studied in the looking-while-listening paradigm, which

measures infants' fixation on a target object (vs. a distractor) after hearing a target label.

We present a large-scale, open database of infant and toddler eye-tracking data from

looking-while-listening tasks. The goal of this effort is to address theoretical and

methodological challenges in measuring vocabulary development. [tools; processing; analysis/

Peekbank: Exploring children's word recognition through an open, large-scale repository for developmental eye-tracking data 39

Introduction

Across their first years of life, children learn words in their native tongues at a rapid 41 pace (Frank, Braginsky, Yurovsky, & Marchman, 2021). [notes about the size/pace] A key 42 part of the word learning process is children's emerging ability to rapidly process words and link them to relevant meanings – often referred to as word recognition. Measuring early word recognition offers insight into children's early word representations and the processes 45 supporting early language comprehension (Bergelson, 2020). Word recognition skills are also thought to build a foundation for children's subsequent language development. Past research has found that early word recognition efficiency is predictive of later linguistic and general cognitive outcomes (Bleses, Makransky, Dale, Højen, & Ari, 2016; Marchman et al., 2018). While word recognition is a central part of children's language development, mapping the trajectory of word recognition skills has remained elusive. Studies investigating children's word recognition are typically limited in scope to experiments in individual labs involving small samples tested on a limited set of items. This limitation in scale makes it difficult to understand developmental changes in children's word knowledge at a broad scale. Peekbank provides an openly accessible database of eye-tracking data of children's word recognition, with the primary goal of facilitating the study of developmental changes in children's word knowledge and recognition speed.

The "Looking-While-Listening" Paradigm

- Word recognition is traditionally studied in the "looking-while-listening" paradigm 59 (alternatively referred to as the intermodal preferential looking procedure; Fernald, Zangl, Portillo, & Marchman, 2008; Hirsh-Pasek, Cauley, Golinkoff, & Gordon, 1987). In such studies, infants listen to a sentence prompting a specific referent (e.g., Look at the dog!) while viewing two images on the screen (e.g., an image of a dog – the target image – and an

- image of a duck the distractor image). Infants' word recognition is measured in terms of
 how quickly and accurately they fixate on the correct target image after hearing its label.

 Past research has used this same basic method to study a wide range of questions in
 language development. For example, the looking-while-listening paradigm has been used to
- $_{68}$ $\,$ uncover early knowledge of nouns in infants' early noun knowledge, phonological
- 69 representations of words, prediction during language processing, and individual differences in
- 170 language development (Bergelson & Swingley, 2012; Golinkoff, Ma, Song, & Hirsh-Pasek,
- ⁷¹ 2013; Lew-Williams & Fernald, 2007; Marchman et al., 2018; Swingley & Aslin, 2000).

72 Measuring developmental change in word recognition

While the looking-while-listening paradigm has been highly fruitful in advancing 73 understanding of early word knowledge, fundamental questions remain both about the trajectory of children's word recognition ability and the nature of the method itself. One central question is how to measure developmental change in word recognition. A key idea in the language learning literature is that processing speed - the ability to quickly link a word with its referent - supports language learning. Age-related changes in speed of processing are thought to accelerate infants' subsequent language learning: the faster infants are able to 79 process incoming speech input, the better able they become to learn from their language environment. Similarly, longitudinal analyses have found that individual differences in word 81 recognition speed predict linguistic and cognitive outcomes later in childhood (e.g., 82 Marchman & Fernald, 2008). However, measuring increases in the speed and accuracy of 83 word recognition faces the challenge of distinguishing developmental changes in word recognition skill from changes in knowledge of specific words. This problem is particularly 85 thorny in child development, since the number of items that can be tested within a single session is limited and items must be selected in an age-appropriate manner (Peter et al., 2019). Measuring developmental change therefore requires large-scale datasets with a range of items, in order to generalize age-related changes across words.

Developing methodological best-practices

A second question relates to evaluating methodological best practices. In particular,
many fundamental analytic decisions vary substantially across studies, and different decisions
may lead to different inferences about children's word recognition. For example, researchers
vary in how they select time windows for analysis, transform the dependent measure of target
fixations, and model the time course of word recognition (Csibra, Hernik, Mascaro, Tatone,
Lengyel, 2016; Fernald et al., 2008; Huang & Snedeker, 2020). This problem is made more
complex by the fact that many of these decisions depend on a variety of design-related and
participant-related factors (e.g., infant age). Establishing best practices therefore requires a
large database of infant word recognition studies varying across such factors, in order to test
the potential consequences of methodological decisions on study results.

Peekbank: An open database of developmental eye-tracking studies.

What these two questions share is that they are difficult to answer at the scale of a 102 single study. To address this challenge, we introduce Peekbank, a flexible and reproducible 103 interface to an open database of developmental eye-tracking studies. The Peekbank project 104 (a) collects a large set of eye-tracking datasets on children's word recognition, (b) introduces 105 a data format and processing tools for standardizing eye-tracking data across data sources, 106 and (c) provides an interface for accessing and analyzing the database. In the current paper, 107 we give an overview of the key components of the project and some initial demonstrations of 108 its utility in advancing theoretical and methodological insights. We report two analyses 109 using the database and associated tools (N=1,233): (1) a growth curve analysis modeling 110 age-related changes in infants' word recognition while generalizing across item-level 111 variability; and (2) a multiverse-style analysis of how a central methodological decision – 112 selecting the time window of analysis – impacts inter-item reliability. 113

Design and Technical Approach

Database Framework.

114

One of the main challenges in compiling a large-scale eye-tracking dataset is the lack of
a shared re-usable data format across individual experiments. Researcher conventions for
structuring data vary, as do the technical specifications of different devices, rendering the
task of integrating datasets from different labs and data sources difficult. Therefore, our first
effort was developing a common, tidy format for the eye-tracking data in Peekbank to ease
the process of conducting cross-dataset analyses (Wickham et al., 2019). All incoming
datasets will be processed into this unified format and then ingested into the core database.

As illustrated in Figure XX, the Peekbank framework consists of three main 123 components: (1) processing eye-tracking experimental datasets into a unified format; (2) 124 populating a relational database; and (3) providing an interface to the database. These 125 components are supported by three libraries. The peekds library (for the R language; R 126 Development Core Team, 2020) helps researchers convert and validate existing datasets to 127 use the relational format of the database. The peekbank module (Python) creates a 128 database with the relational schema and populates it with the standardized datasets 129 produced by peekds. The database is implemented in MySQL, an industry standard 130 relational database, which may be accessed by a variety of programming languages over the 131 internet. The peekbankr library (R) provides an application programming interface, or API, 132 that offers high-level abstractions for accessing data in Peekbank. 133

In the following sections, we will begin by providing the details on the database's scheme design and technical implementation on peekds. For users who are primarily interested in accessing the database can skip these details and focus on access through the peekbankr API and the web apps.

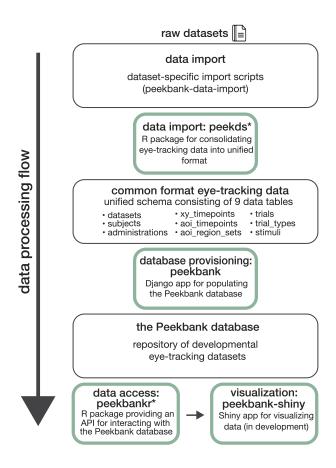

Figure 1. Overview of the Peekbank data ecosystem. Peekbank tools are highlighted in green. *custom R packages.

Database Schema

139

140

141

The peekbank database has two main sets of data: (1) metadata on the experiment design and participants and (2) timecourse looking data (Fig XX). Here, we will give an outline of the tables encoding this data.

Metadata. Metadata can be separated into two parts: (1) subject-level
demographics and (2) trial structure information. Subject-level information includes the
subjects table, information about individuals who participated in the study, and the
administrations table, information about runs of the experiment. The subjects table
contains information at the subject level, such as a subject's sex and native language, and
the administrations table includes information specific to a particular run of the

experiment, such as the subject's age at the time of the experiment and the eyecoding method for that administration.

The stimuli and trial_types tables store information about the experiment design.

Stimuli are (label, image) mappings that are seen in the experiment. The trial_types table

encodes information about each trial of the experiment including the target stimulus and

location, the distractor stimulus and location, and the point of disambiguation for that trial.

If this dataset used automatic eyetracking rather than manual coding, each trial type is

additionally linked to a set of area of interest (x, y) coordinates, encoded in the

aoi_region_sets table.

Because individual trial types can be repeated multiple times within an administration,
the order of the trials is encoded in the trials table. Each unique ordering that occurred in
the experiment is encoded—for example, if every participant saw the same ordering, the
trials table would only have as many rows as there were trials in the experiment; if there
were many different orderings, the trials table would represent each ordering. The trial_id,
which links a trial type to the order it was presented in an administration, is attached to the
time course looking data.

Timecourse data. Timecourse looking data is encoded in two tables: 164 aoi_timepoints and xy_timepoints. The aoi_timepoints table encodes time-stamped 165 looks to areas of interest: looks to the target, looks to the distractor, looks to other places, 166 and missing looks. All datasets have this table, and it is the centerpiece of the schema where 167 looking behavior is recorded. Additionally, for eyetracking data that is automatically rather 168 than manually coded, the xy_timepoints table encodes the (x, y) coordinates of looks over 169 the course of the experiment. Both the aoi_timepoints and xy_timepoints tables are 170 resampled to a consistent sampling rate, as described in the Import section below. 171

172 Import

During data import, raw eye-tracking datasets are processed to conform to the
Peekbank data schema. The following section is a description of the import process for
peekbank. It serves as both a description of our method in importing the datasets already in
the database, as well as a high-level overview of the import process for researchers looking to
import their data in the future. First, we will describe the import of metadata, and second,
we will describe import of the timecourse looking data, including processing functions in
peekds for normalizing and resampling looking behavior.

Metadata. Subject-level data is imported for all participants who have experiment
data. In general, we import data without particular exclusions, including as many
participants as possible in the database. The subjects and administrations tables
separate information at the subject level from information about runs of the experiment,
such that longitudinal studies have multiple administrations linked to each subject.

The stimuli table has a row for each (word, image) pair, and thus is used slightly 185 differently across different experiment designs. In most experiments, there is a one-to-one 186 mapping between images and labels (e.g., each time an image of a dog appears it is referred 187 to as "dog"). For studies in which there are multiple potential labels per image (e.g., "dog" 188 and "chien" are both used to refer to an image of a dog), images can have multiple rows in 189 the stimuli table with unique labels as well as a row with no label to be used when the 190 image appears solely as a distractor (and thus its label is ambiguous). This structure is 191 useful for studies on synonymy or using multiple languages. For studies in which the same 192 label refers to multiple images (e.g., the word "dog" refers to an image of a dalmatian and a 193 poodle), the same label can have multiple rows in the stimuli table with unique images. 194 The trial types table contains each pair of stimuli, a target and distractor, seen in the 195 experiment. The trial types table links trial types to the aoi region sets table and the 196 trials table. 197

The trials table encodes each unique ordering of trial types seen in all runs of an experiment. For example, for experiments with a fixed trial order, the trials table will have as many rows as there are stimuli in the experiment; for experiments with a randomized trial order, there will be many rows linking the trial orderings to the trial types. The trials table links all experiment design information to the timecourse data.

Timecourse data. Raw looking data is a series of looks to AOIs or to (x, y) 203 coordinates on the experiment screen, linked to points in time. For data generated by 204 eyetrackers, we typically have (x, y) coordinates at each time point, which will be encoded in 205 the xy timepoints table. These looks will also be recoded into AOIs using the AOI 206 coordinates in the aoi region sets table using the add aois() function in peekds, which 207 will be encoded in the aoi_timepoints table. For hand-coded data, we typically have a 208 series of AOIs; these will be recoded into the categories in the Peekbank schema (target, 200 distractor, other, and missing) and encoded in the aoi timepoints table, and these 210 datasets will not have an xy_timepoints table. 211

Typically, timepoints in the xy_timepoints table and aoi_timepoints table need to
be regularized to center each trial's time around the point of disambiguation—the time of
target word onset in the trial. If time values run throughout the experiment rather than
resetting to zero at the beginning of each trial, rezero_times() is used to reset the time at
each trial. After this, each trial's times are centered around the point of disambiguation
using normalize_times(). When these steps are complete, the time course is ready for
resampling.

To facilitate time course analysis and visualization across datasets, timecourse data
must be resampled to a uniform sampling rate. To do this, we use the resample() function.
During the resampling process, we interpolate using constant interpolation, selecting the
looking location for the nearest time point in the original data for both aoi_timepoints
and xy_timepoints data. Compared to linear interpolation (see e.g. Wass et al., 2014),

constant interpolation has the advantage that it does not introduce new look locations, so it is a more conservative method of resampling.

After resampling, the final step of dataset import is validation. The peekds package
offers functions to check the now processed data tables against the most updated database
schema to ensure that all tables have the required fields and correct data types for database
ingestion. In an effort to double check the data quality and to make sure that no errors are
made in the importing script, we also create a time course plot based on our processed tables
to replicate the results in the original paper in the validation step.

²³² CHECK and edit resampling section for ties and for maximum time over which

Table 1

245

Overview over the datasets in the current database.

234 Current Data Sources.

The database currently includes 11 looking-while-listening datasets comprising 235 N=1320 total participants (Table XX). Most datasets (10 out of 11 total) consist of data 236 from monolingual native English speakers. They span a wide age spectrum with participants 237 ranging from 8 to 84 months of age, and are balanced in terms of gender (48% female). The 238 datasets vary across a number of dimensions related to design and methodology, and include 239 studies using manually coded video recordings and automated eye-tracking methods (e.g., 240 Tobii, EyeLink) to measure gaze behavior. Most studies focused on testing familiar items, 241 but the database also includes studies with novel pseudowords. All data (and accompanying references) are openly available on the Open Science Framework (https://osf.io/pr6wu/?view_only=07a3887eb7a24643bdc1b2612f2729de).

Interfacing with peekbank

250 Shiny App

249

260

261

One goal of the Peekbank project is to allow a wide range of users to easily explore and learn from the database. We therefore have created an interactive web application — peekbank-shiny — that allows users to quickly and easily create informative visualizations of individual datasets and aggregated data. peekbank-shiny is built using Shiny, a software package for creating web apps using R. The Shiny app allows users to create commonly used visualizations of looking-while-listening data, based on data from the Peekbank database. Specifically, users can visualize

- 1. the time course of looking data in a profile plot depicting infant target looking across trial time,
 - 2. overall accuracy (proportion target looking) within a specified analysis window,
 - 3. reaction times (speed of fixating the target image) in response to a target label, and
- 4. an onset-contingent plot, which shows the time course of participant looking as a function of their look location at the onset of the target label.

Users are given various customization options for each of these visualizations, e.g.,
choosing which datasets to include in the plots, controlling the age range of participants,
splitting the visualizations by age bins, and controlling the analysis window for time course
analyses. Plots are then updated in real time to reflect users' customization choices, and
users are given options to share the visualizations they created. The Shiny app thus allows
users to quickly inspect basic properties of Peekbanks datasets and create reproducible
visualizations without incurring any of the technical overhead required to access the

271 database through R.

Peekbank in Action

We provide two potential use-cases for Peekbank data. In each case, we provide sample code so as to model how easy it is to do simple analyses using data from the database. Our 280 first example shows how we can replicate the analysis for a classic study. This type of 281 computational reproducibility can be a very useful exercise for teaching students about best 282 practices for data analysis (e.g., Hardwicke et al., 2018) and also provides an easy way to 283 explore looking-while-listening timecourse data in a standardized format. Our second 284 example shows an in-depth exploration of developmental changes in the recognition of 285 particular words. Besides its theoretical interest (which we will explore more fully in 286 subsequent work), this type of analysis can be used for optimizing the stimuli for new 287 experiments. 288

Discussion/ Conclusion

Theoretical progress in understanding child development requires rich datasets, but collecting child data is expensive, difficult, and time-intensive. Recent years have seen a growing effort to build open source tools and pool research efforts to meet the challenge of building a cumulative developmental science (Bergmann et al., 2018; Frank, Braginsky, Yurovsky, & Marchman, 2017; The ManyBabies Consortium, 2020). The Peekbank project expands on these efforts by building an infrastructure for aggregating eye-tracking data across studies, with a specific focus on the looking-while-listening paradigm. This paper presents an illustration of some of the key theoretical and methodological questions that can be addressed using Peekbank: generalizing across item-level variability in children's word recognition and providing data-driven guidance on methodological choices.

There are a number of limitations surrounding the current scope of the database. A 309 priority in future work will be to expand the size of the database. With 11 datasets currently 310 available in the database, idiosyncrasies of particular designs and condition manipulations 311 still have substantial influence on modeling results. Expanding the set of distinct datasets will allow us to increase the number of observations per item across datasets, leading to more 313 robust generalizations across item-level variability. The current database is also limited by 314 the relatively homogeneous background of its participants, both with respect to language 315 (almost entirely monolingual native English speakers) and cultural background (all but one 316 dataset comes from WEIRD populations; Muthukrishna et al., 2020). Increasing the 317 diversity of participant backgrounds and languages will expand the scope of the 318 generalizations we can form about child word recognition. Finally, while the current 319 database is focused on studies of word recognition, the tools and infrastructure developed in 320 the project can in principle be used to accommodate any eye-tracking paradigm, opening up 321 new avenues for insights into cognitive development. Gaze behavior has been at the core of 322 many of the key advances in our understanding of infant cognition. Aggregating large 323 datasets of infant looking behavior in a single, openly-accessible format promises to bring a 324 fuller picture of infant cognitive development into view. 325
